Intro

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

Let's begin with the Basel problem, first posed in 1644 by Mengoli. *Find the sum of the following infinite series:* 

$$\sum_{n=1}^{\infty} \frac{1}{n^2} = 1 + \frac{1}{4} + \frac{1}{9} + \frac{1}{16} + \dots$$

Let's begin with the Basel problem, first posed in 1644 by Mengoli. *Find the sum of the following infinite series:* 

$$\sum_{n=1}^{\infty} \frac{1}{n^2} = 1 + \frac{1}{4} + \frac{1}{9} + \frac{1}{16} + \dots = \frac{\pi^2}{6}$$

• First solved\* by Euler in 1735

$$\sin(\pi x) = \pi x - \frac{(\pi x)^3}{3!} + \frac{(\pi x)^5}{5!} + \dots$$
$$\sin(\pi x) = \pi x (1 - x^2) \left(1 - \frac{x^2}{4}\right) \left(1 - \frac{x^2}{9}\right) \dots$$
$$= \pi x + \pi x^3 \left(1 + \frac{1}{4} + \frac{1}{9} + \dots\right) + \pi x^5 (\dots) + \dots$$

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 - のへで

Let's begin with the Basel problem, first posed in 1644 by Mengoli. *Find the sum of the following infinite series:* 

$$\sum_{n=1}^{\infty} \frac{1}{n^2} = 1 + \frac{1}{4} + \frac{1}{9} + \frac{1}{16} + \dots = \frac{\pi^2}{6}$$

• First solved\* by Euler in 1735

$$\sin(\pi x) = \pi x - \frac{(\pi x)^3}{3!} + \frac{(\pi x)^5}{5!} + \dots$$
$$\sin(\pi x) = \pi x (1 - x^2) \left(1 - \frac{x^2}{4}\right) \left(1 - \frac{x^2}{9}\right) \dots$$
$$= \pi x + \pi x^3 \left(1 + \frac{1}{4} + \frac{1}{9} + \dots\right) + \pi x^5 (\dots) + \dots$$

- Euler's proof was incomplete; he assumed that a power series can be written as an infinite product of linear polynomials.
  - It's actually true in this case, but not always
- There are about a dozen other crazy ways to prove this.

Intro

Riemann's zeta function:

$$\zeta(s) = \sum_{n=1}^\infty \frac{1}{n^s}$$

- This series converges for real numbers s>1, diverges for real numbers  $s\leq 1$
- s = 1 is the harmonic series  $\sum_{n=1}^{\infty} \frac{1}{n}$
- The Basel problem is really asking "what is the value of  $\zeta(2)?"$  complex function

### The Euler product formula

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

A prime number is a natural number whose only divisors are 1 and itself.

Here's the simplest connection between the zeta function and prime numbers:

$$\prod_{p} \left( \frac{1}{1 - p^{-s}} \right) = \prod_{p} \left( \sum_{k=0}^{\infty} (p^{-s})^{k} \right) = \prod_{p} \left( \sum_{k=0}^{\infty} (p^{k})^{-s} \right)$$
$$= \left( 1 + 2^{-s} + (2^{2})^{-s} + \dots \right) \left( 1 + 3^{-s} + (3^{2})^{-s} + \dots \right) \cdots$$
$$= 1^{-s} + 2^{-s} + (2^{2})^{-s} + 5^{-s} + (2 \cdot 3)^{-s} + 7^{-s} + (2^{3})^{-s} + \dots$$
$$= \sum_{n=1}^{\infty} \frac{1}{n^{s}} = \zeta(s).$$

### An application of the Euler product

#### Theorem

Let  $X = \{x_1, x_2, ..., x_s\}$  be a set of s randomly chosen integers. Let P be the probability that gcd(X) > 1. Then  $P = 1/\zeta(s)$ .

- Let p be a prime.  $P(x_i \text{ is divisible by } p) = 1/p$ .
- $P(s \text{ random numbers are all divisible by } p) = (1/p)^s$
- $P(\text{at least one } x_i \text{ is not divisible by } p) = 1 p^{-s}$
- Probability that there is no prime which divides all  $x_i$  is the product of this expression over all primes:

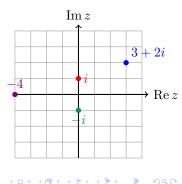

$$P = \prod_{p} (1 - p^{-s})$$
$$= \frac{1}{\zeta(s)}.$$

 $\zeta(s)$  was studied first by Euler as a real function. Riemann was the first to view it as a complex function.

#### Definition

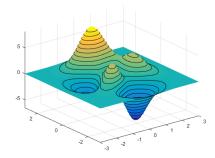

Let *i* be an imaginary number with  $i^2 = -1$ . Complex numbers are expressions of the form a + bi where  $a, b \in \mathbb{R}$ . We call this set  $\mathbb{C}$ .

- Let z = a + bi. The real part of z is  $\operatorname{Re}(z) = a$  and the imaginary part is  $\operatorname{Im}(z) = b$ .
- View these as points in the complex plane, i.e.  $(x, y) = (\operatorname{Re} z, \operatorname{Im} z)$ .
- Magnitude of z is  $|z| = \sqrt{a^2 + b^2}$ (distance from z to the origin)

### Two minute intro to complex numbers part 2

- You can add, subtract, multiply, and divide complex numbers
- You can make a function whose input and output are complex numbers, e.g.  $f(z) = z^2$ 
  - $f(2+i) = (2+i)^2 = 2^2 + i^2 + 2 * 2 * i = 3 + 4i$
- Hard to graph because both domain and range are 2 dimensional

MathWorks

### The complex zeta function

$$\zeta(s) = \sum_{n=1}^{\infty} \frac{1}{n^s} = \prod_p \left(1 - p^{-s}\right)^{-1}$$

Riemann described the complex zeta function in his 1859 paper Über die Anzahl der Primzahlen unter einer gegebenen Grösse.

- $\zeta(s)$  converges for all  $s \in \mathbb{C}$  with  $\operatorname{Re} s > 1$
- There is a meromorphic continuation of ζ(s) to the rest of C (with a simple pole at s = 1)

$$\zeta(s) = \frac{\Gamma(1-s)}{2\pi i} \int_C \frac{(-z)^s}{e^z - 1} \frac{dz}{z}$$

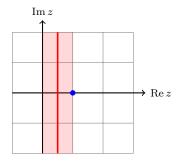

•  $\zeta(s)$  satisfies a functional equation:

$$\zeta(s) = 2^s \pi^{s-1} \sin\left(\frac{\pi s}{2}\right) \Gamma(1-s) \zeta(1-s)$$

### The Riemann Hypothesis

▲ロト ▲帰ト ▲ヨト ▲ヨト 三日 - の々ぐ

The functional equation  $\zeta(s) = 2^s \pi^{s-1} \sin\left(\frac{\pi s}{2}\right) \Gamma(1-s) \zeta(1-s)$ relates values on opposite sides of the critical line  $\operatorname{Re} z = 1/2$ :

It's known that all\* zeros of  $\zeta(s)$  lie in the critical strip  $0 < \operatorname{Re} z < 1$ .

## The Riemann hypothesis

#### Conjecture (Riemann hypothesis)

All nontrivial zeros of  $\zeta(s)$  have real part 1/2.

- There are trivial zeroes at all negative even integers
- This is one of the most famous unsolved problems in all of mathematics. If you can solve it, you'll get \$1 million and probably a Fields medal.
- Why is this important?
  - $\zeta(s)$  encodes lots of deep information about  $\mathbb Z$
  - Meromorphic complex functions are largely defined by the locations and orders of their zeros and poles.
  - Knowing the zeros is important for computing contour integrals. (more on this later)

- Number theory: branch of mathematics that studies the integers,  $\ensuremath{\mathbb{Z}}$
- However, in order to understand  $\mathbb Z$  we often have to work with other mathematical objects:
  - $\mathbb{Q}$  (rational numbers) and  $\mathbb{C}$  (complex numbers)
  - Finite fields  $\mathbb{F}_q$  (modular arithmetic)
  - Rings and fields of polynomials, e.g.  $\mathbb{Z}[t]$ ,  $\mathbb{F}_q(t)$
  - Geometric objects like algebraic curves
- Goal is to understand arithmetic in Z. A major part of this is understanding how composite numbers break down into primes.
  - Another major part is understanding integer solutions to equations like  $x^2-ny^2=1$

### Theorem (PNT)

Let  $\pi(x) = \# \{ p \in \mathbb{Z} : p \le x \}$  be the prime counting function. As  $x \to \infty$ ,  $\pi(x) \sim x/\log x$ . That is,

$$\lim_{x \to \infty} \frac{\pi(x)}{x/\log x} = 1.$$

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

Instead of working with  $\pi(x)$  directly, we'll use the von Mangoldt function

$$\Lambda(n) = \begin{cases} \log p & \text{if } n = p^k \\ 0 & \text{otherwise} \end{cases}$$

and the Chebyshev function

$$\psi(x) = \sum_{n \le x} \Lambda(n).$$

The PNT is equivalent to proving that  $\lim_{x\to\infty} \frac{\psi(x)}{x} = 1$ .

#### Proving the Prime Number Theorem

Here's where  $\zeta(s)$  comes in: it turns out that

$$-\frac{d}{ds}\log\zeta(s) = \sum_{n=1}^{\infty} \Lambda(n)n^{-s}.$$

Then you can do some analysis and prove the following equation:

$$\psi(x) = x - \sum_{\rho} \frac{x^{\rho}}{\rho} - \log(2\pi)$$

summing over the zeros  $\rho$  of  $\zeta(s)$ . If you know where the  $\rho$  are, you can prove that this is  $\psi(x) = x - (\text{lower order terms})$ .

Or compute a certain contour integral in the complex plane. Again, need to know the zeros of  $\zeta(s)$ .

### Proving the Prime Number Theorem

(日) (同) (三) (三) (三) (○) (○)

- Riemann stated his hypothesis in 1859. For decades afterwards, mathematicians knew that proving the RH would prove the PNT.
- 1896: Hadamard and de la Vallée-Poussin (independently) proved that all nontrivial zeros of  $\zeta(s)$  lie in the critical strip  $0 < \text{Re} \, z < 1$ .
  - This is weaker than the RH, but it's enough to prove the PNT
- An even better estimate is  $\pi(x) = \int_2^t \frac{1}{\log t} dt$ .

- There are still many unanswered questions about the distribution of primes in Z, e.g. twin prime conjecture
- For the past few decades, prime numbers (and number theory in general) have become important because of their use in crypto algorithms
- There are other zeta functions (and *L*-functions) for other types of mathematical objects such as number fields, varieties, representations...
  - Extended/Generalized Riemann Hypothesis (ERH/GRH): RH for other types of zeta functions
  - Many number theory papers prove important results if the GRH is true!
